MDM platform: what is IN THE APPLICATION today

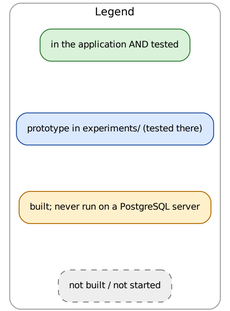

updated 2026-10-16 | ONE matching engine, the kernel, decides every record however it arrives | the older engines remain only for rollback and comparison

WHAT REMAINS: from one engine to the 100-million-record target

updated 2026-10-16 | the kernel is already the application's engine (previous page); these are the steps not yet built, in order | target: 100 million records in 12 hours = about 2,315 records per second

Also not in the application yet (prototype only, or not built)

- The kernel on a live PostgreSQL
its call pattern has never run there (runbook steps 6 to 8)
- Tier 3: an agent that may RESOLVE items
the read-only tier and recording a recommendation exist (page 1; the table is agent_recommendations) and so does the replay that tests an agent on past decisions; the runner exists in shadow mode (it records, a person decides); auto-resolve is design only
- A disagreement report
records where the kernel and the legacy engine differ, for a steward to label
- Per-tenant engine setting
(MDM_ENGINE is global today)
- 'anchored' update setting
(a record stays while it shares an identifier): prototype
- Replayable event outbox for downstream systems
prototype
- Relationships between groups (households)
linked, not merged: prototype
